

EXPERIMENTAL AND SIMULATION ANALYSIS FOR PERFORMANCE  
ENHANCEMENT OF ELLIPTICAL SAVONIUS WIND TURBINE BY  
MODIFYING BLADE SHAPES

SALIH MERI ABDUL RIDHA

A thesis submitted in fulfilment of the requirement for the award of the  
Doctor of Philosophy of Mechanical Engineering

Faculty of Mechanical and Manufacturing Engineering  
Universiti Tun Hussein Onn Malaysia

NOVEMBER 2019

## ACKNOWLEDGEMENTS

*In the name of Allah, the Most Merciful*

I would like to thank ALLAH S.W.T for blessing me and giving me the strength to complete this thesis. My deepest thanks to my beloved mother and family for their encouragement and prayer.

Special appreciation goes to my supervisor, Dr. Hamidon bin Salleh, for his guidance, patience and endless encouragement throughout this project. Under his guidance, I was able to finish my project within the scope of work and accomplish the objectives of the project.

I would also like to thank the Faculty of Mechanical and Manufacturing Engineering, University Tun Hussein Onn Malaysia (UTHM), and Iraqi Cement State Company, Ministry of Industry and Minerals, Baghdad, Iraq, for their financial and moral support in accomplishing this work.

## ABSTRACT

Savonius turbines are drag-based rotors which operate due to a pressure difference between the advancing and retreating blades. After going through an exhaustive literature review, it was realized that the Savonius wind turbines are an applicable option at low wind speed areas, where the counterpart of these turbines cannot work efficiently. Nevertheless, the existing design is still under research to make it more applicable in urban areas. Therefore, the research objective was to develop and test an elliptical Savonius wind turbine to improving its performance in terms of power and torque coefficients by modifying blade shapes and overlap ratio. In the beginning, a series of 2D unsteady simulations (CFD-Fluent version 19.1) of the Savonius elliptical turbine has been performed to study the overlap ratio of blades and the effect of the turbulence models. Conventional elliptical Savonius turbine was modified by changing the overlap ratio from the value (OR=0.15) to (OR=0.2) and called as the Model-A. Then, the concave surface of the blade Model-A was modified (as zigzag shape) and called as Model-B. The blade shape of the Model-B was modified by adding bypass channels for each blade to creating new configuration was called the Model-C. The experimental work begins with the manufacturing of the models (A, B and C) of the blade using 3D printing technology. Models were tested by the wind tunnel in Aerodynamic laboratory (UTHM) with four cases of wind velocity. 2D simulation result for Model-A at OR= 0.2, where the increase in maximum power coefficient value obtained was 3.85% and 7.69% compared to overlap ratio (0.15 and 0.1), respectively. The result of the experimental test was obtained the maximum power coefficient (0.296, 0.292, 0.291, and 0.295) at wind velocity (6 m/s, 8 m/s, 9 m/s, and 10 m/s), respectively for Model-B. The Model-C result in the maximum power coefficient (0.28) compared with Model-A (0.26). The 3D unsteady simulation also has been done to visualisation the behaviour of flow around Model-B and it show a good agreement with experimental test results.

## ABSTRAK

Turbin Savonius adalah rotor berasaskan seret yang beroperasi disebabkan oleh perbezaan tekanan antara bilah pemaju dan pengunduran. Selepas melalui kajian literatur yang menyeluruh, ternyata bahawa turbin angin Savonius adalah pilihan yang sesuai di kawasan angin laju dipermukaan yang rendah, di mana rakan sejana turbin ini tidak dapat berfungsi dengan cekap. Walau bagaimanapun, reka bentuk yang sedia ada masih dalam penyelidikan untuk menjadikannya lebih sesuai di kawasan bandar. Oleh hal yang demikian, objektif penyelidikan adalah untuk membangun dan menguji turbin angin Savoyus elips untuk meningkatkan prestasinya dari segi kuasa dan koefisien tork dengan mengubah bentuk bilah dan nisbah pertindihan. Pada mulanya, satu siri 2D simulasi yang tidak mantap (CFD-Fluent versi 19.1) dari turbin elips Savonius telah dilakukan untuk mengkaji nisbah pertindihan bilah dan kesan model pergolakan. Turbin unggun konvensional Savonius diubahsuai dengan menukar nisbah bertindih daripada nilai ( $OR = 0.15$ ) ke ( $OR = 0.2$ ) dan dipanggil sebagai Model-A. Kemudian, permukaan cekung pada bilah Model-A diubahsuai (sebagai bentuk zigzag) dan dikenali sebagai Model-B. Bentuk bilah Model-B diubahsuai dengan menambah saluran pintasan untuk setiap bilah untuk membuat konfigurasi baru dipanggil Model-C. Kerja eksperimen bermula dengan pembuatan model (A, B dan C) bilah menggunakan teknologi percetakan 3D. Model telah diuji oleh terowong angin di makmal Aerodinamik (UTHM) dengan empat kes kelajuan angin. Hasil simulasi 2D untuk Model-A pada  $OR = 0.2$ , di mana peningkatan nilai koefisien maksimum yang diperoleh adalah 3.85% dan 7.69% berbanding dengan nisbah tertindih (0.15 dan 0.1). Keputusan uji kaji eksperimen diperolehi dengan pekali kuasa maksimum (0.296, 0.292, 0.291, dan 0.295) pada kelajuan angin (6 m / s, 8 m / s, 9 m / s, dan 10 m / s) masing-masing untuk Model-B. Model-C menghasilkan pekali kuasa maksimum (0.28) berbanding Model-A (0.26). Simulasi tidak stabil 3D juga telah dilakukan untuk menggambarkan kelakuan aliran di sekitar Model-B dan ia menunjukkan persetujuan yang baik dengan hasil ujian eksperimen.

## LIST OF SYMBOLS AND ABBREVIATIONS

### Abbreviations

AR	- Aspect ratio
CFD	- Computational fluid dynamics
HAWT	- Horizontal axis wind turbine
H-Rotor	- VAWT with straight blades
OR	- Overlap ratio
RPM	- Revolution per minute [N]
SINPLE	- Semi implicit linked equations
SST	- Shear stress transport
TSR	- Tip-speed ratio [ $\lambda$ ]
VAWT	- Vertical axis wind turbine

### Notations

$A$	- Swept area of the turbine [ $\text{m}^2$ ]
$d$	- Chord length of the blades [m]
$D$	- Outer diameter of the turbine [m]
$D_o$	- End plate diameter [m]
$e$	- Blade overlap distance [m]
$H$	- Blade height [m]
$F$	- Force [N]
$I$	- Electric current [Amp]
$k$	- Turbulence kinetic energy [ $\text{m}^2 \text{s}^{-2}$ ]
$P$	- Pressure [Pascal]
$P_{available}$	- Power available in the wind [w]
$P_f$	- Power coefficient
$P_{turbine}$	- Turbine power output [w]

$R$	- Rotor radius [m]
$Re$	- Reynolds number
$s$	- Separation Gap [m]
$T$	- Dynamic Torque [Nm]
$T_f$	- Torque coefficient
$U$	- Free stream wind speed [m/s]
$V$	Electric voltage [volt]

#### Greek symbols

$\varepsilon$	- Energy dissipation rate [ $\text{m}^2 \text{s}^{-2}$ ]
$\sigma$	- Turbine solidity
$\rho$	- Density of air ( $\text{kg/m}^3$ )
$\mu$	- Dynamic viscosity [ $\text{kg/(m s)}$ ]
$\theta$	- Turbine rotational angle [ $^\circ$ ]
$\eta_{Gen}$	- Generator efficiency
$\omega$	- Angular speed of the turbine [Rad/s]

## CHAPTER 1

### INTRODUCTION

In previous years, there has been increasing interest in the sustainable generation of electricity due to the uncontrolled exploitation of conventional energy resources which as well as issues related to energy production such as environmental pollution and global warming. As a result, interest in energy issues has shifted to the search for alternative sources such as solar, tide, biomass and wind energy. This has been reviewed and studied in terms of the size of power plants and the direction of the transformation of central electric stations to small stations distributed throughout the country as well as the conversion of energy produced by wind energy. To achieve the highest possible level of electric power production, wind turbines were properly installed to be in the wind farm.

The analysis also showed that most nationally determined contribution (NDCs) underestimated the potential of renewable energy, the technological learning rate, rapid cost reductions and innovation that were bound to continue over the coming years. With more ambitious yet credible commitment to renewable energy, by year 2030, renewables can achieve up to five times the carbon dioxide ( $CO_2$ ) mitigation reflected in current NDCs. Combined with significant energy efficiency gains, further reliance on renewable energy could halve the estimated annual carbon dioxide ( $CO_2$ ) emissions to about 20 giga tonnes (Gt) in 2030. This would be enough to keep the world on a  $2C^\circ$  pathway, with continuing advances thereafter (see Figure 1.1) (Adnan Z. Amin, 2017). Therefore, researchers focused on studying the use of wind energy to take advantage of the disposal of  $CO_2$  pollutants and obtain the maximum electric power from them. There are two main types of WTs, which are the horizontal axis wind turbines (HAWT) and the vertical axis wind turbines (VAWT), where each of

these WT has their respective advantages and disadvantages. In comparison to HAWT, catching the wind from all directions is the major feature of VAWT, which does not require the yaw mechanism (Li et al., 2016; Ross & Altman, 2011). With a simple structure, less commotion and little operation space, VAWT is more appropriate for urban zones where the wind stream is exceedingly turbulent and conflicting (Bhutta et al., 2012; Rashidi, Kadambi, & Chinchore, 2014). Nonetheless, the main problems of the VAWT consist of having small efficiency and difficult self-starting (Bhutta et al., 2012; Eriksson, Bernhoff, & Leijon, 2008).

Figure 1.1: Global energy-related ( $CO_2$ ) emissions between 2010 to 2050 (Adnan Z. Amin -Director-General/ IRENA, 2017)

## 1.1 Background of the Study

The two fundamentals of wind turbines are the HAWTs and VAWTs. Every single model of wind turbine, for the most part, belongs to one of these classifications. However, the world market is ruled by HAWT. Different plans have been proposed in the past to lessen the cost and increase the performance of wind turbines. The division of types of wind turbines depends on the direction of shaft rotation relative to the earth's surface, where the HAWT rotation shaft is parallel to the ground surface. In

contrast, the turbines of the VAWT are perpendicular to the surface of the earth as shown in Figure 1.2 (Kozak, 2014).

Figure 1. 2: Wind turbines: HAWT Type and VAWTs Types (Kozak, 2014)

Global wind power generation amounted to 950 TWh in 2016, which was nearly 4% of the total global power generation. Some countries have reached much higher percentages. Denmark produced 42% of its electricity from wind turbines in 2016, the highest figure yet recorded worldwide. In Germany, wind power contributed a new record of 13% of the country's power demand from 2001 to 2016 as shown in Figure 1.3 (Wong et al., 2017).

Figure 1.3: Annual net global wind capacity additions, 2001-2016 (Wong et al., 2017).

There are numerous features of VAWTs which are different to HAWTs. Studies have shown that VAWTs are more appropriate for turbulent flows and urban applications. However, the low total efficiency and low self-start capability of VAWTs are always major disadvantages, mostly for the lift-type VAWTs. Unlike HAWTs, the blade rotation for VAWTs do not generally give positive torque (Wong et al., 2017).

### **1.1.1 Horizontal Axis Wind Turbine (HAWT) Type**

Over the past several years, wind farms generate electricity using HAWTs, which has the highest coefficient of power compared to any other turbines, leading it to be widely used. As shown in Figure 1.4, the general disadvantages of the (HAWT) are the complex structure of the mechanical and electrical parts which require high maintenance, even though it is more efficient than VAWT.

The second problem is the adoption of HAWT at the height of the tower, where the higher the tower, the higher the surface of the earth which then produces more energy. As the rotor and the mechanical and electrical parts are positioned at the top of the tower, the installation and maintenance of the parts incur a higher cost (Spera, 2009). The best increases in mechanical wind capacity can be benefited from the HAWT, by modifying the design of the three-blade turbine. The cross-movement of the tethered blades attracts more attraction on the dynamic energy to reach fast wind flows at the highest altitude (Cherubini, Antonello and Papini, Andrea and Vertechy, Rocco and Fontana, 2015; Goldstein, 2013).

In addition to large wind farms, increasing awareness among people towards clean energy has led to a growing interest in wind energy harvesting within the built environment in an urban area. The complex terrain of the buildings causes a strong deflection of the incoming wind direction. VAWT was identified as the most suitable wind energy extractor under such conditions due to its independence from wind direction in which no yaw mechanism is required. It is well-known that this type of turbine shows lower efficiency and increased oscillations when compared to its horizontal axis competitor. However, the most obvious advantages are its simple design, low cost and operability even in winds of highly changeable intensity and direction which makes them very appealing for both developed urban environments as

well as less developed rural regions that are difficult to access (Svorcan, Stupar, Komarov, Peković, & Kostić, 2013).

Figure 1.4: Rotor efficiency against TSR for different types of turbines (Spera, 2009)

### 1.1.2 Darriues Turbines

Darriues turbines are a type of VAWT that depends on the lift force and mechanism action of the designer, based on the aerodynamics precept of an aircraft. This invention was carried out by F. M. Darrieus (1930) (Devine-Wright, 2005). The airfoil considered in the cross-section of the blades was designed so that the wind would leave longer on the convex side than the other concave side. Therefore, it produces wind speed at its relative value on the convex side. Whether Bernoulli's equation was used or not, it will create differential pressure due to a difference in the wind velocity on the airfoil which in turn will pull its rotor blade around as the wind passes the turbine. Darrieus-type wind turbines consist of two or more rotary blades as shown in Figure

1.6. The rotational speed of Darrieus is high but it requires a high start-up velocity which can be synchronized and combined with an electric generator. Darrieus has a high power efficiency compared to other vertical axis wind turbines based on the drag force. The main problem for Darrieus is the high start-up speed. This has led to the trend of many researchers numerically and experimentally studying the combination of the Savonius rotor and Darrieus rotor to make a hybrid design to acknowledge the Savonius's starting speed (Kang, Liu, & Yang, 2014).

Some researchers have focused on a range of wind turbines in various developed countries to develop and improve VAWT's performance efficiency. These research studies included the development of blade design or the fashioning of vertical axis wind turbines. According to Elkhoury, Kiwata and Aoun (2015), the rotor model H was improved with a variable pitch so that the vertical wind turbine blades can adjust the angle of the pitch to make it spin slightly, resulting in the attack of wind currents in a different angle. Access was increased in the  $P_f$  at all values of the TSR. There were also other similar studies regarding the improvement (Chougule, Rosendahl, & Nielsen, 2015; Zeiner-Gundersen, 2014).

Figure 1.5: Darrieus turbine types (MacPhee & Beyene, 2012)

It is possible to modify the values of the lifting coefficient of a blade through a change in the angle of a blade. This has resulted in an improved performance and had increased the  $P_f$  value of about 43% when compared to the traditional model air

foil blade. (Chougule et al., 2015). Apart from that, a new model for the Savonius rotor was designed using moving blades that were curved to eliminate negative torque and to improve the dynamic performance. The mechanical design was to make the blades open when the blade reverts to the passage of air when the pressure changes on the sides of a rotor (Reupke & Probert, 1991).

A proposal to study a new model of the H-rotor wind turbine for the purpose of developing the rotor capacity for self-starting through the use of internal and external openings in rotor blades was performed. The results of the tests showed that the design had a negative effect on the value of  $P_f$  (Chen, Yang, Yang, & Xu, 2015).

Besides that, a study focusing on the modification of the Darrieus Type-H to increase the mechanical torque coefficients of the turbine was conducted. Positive results were obtained by increasing the force rate of oblique to (40%) (Ismail & Vijayaraghavan, 2015).

## 1.2 Problem Statement

The need for improved alternative energy sources is ever prevalent. Wind energy is one of the most viable renewable sources today due to its year-round availability, and pollution-free nature. However, research of VAWTs has gained a growing interest in recent years because of the opportunities available for small-scale and off-grid power generation which favours the use of vertical-axis turbines.

Savonius wind turbine is a type of vertical axis wind turbine which are drag-based rotors which operate due to a pressure difference between the advancing and retreating blades. The rotor part is a component of a wind turbine which converts the flow of an air mass into mechanical rotational energy. Therefore, this component together with its interface with other components is of utmost importance. Its fabrication and utilization depend on prevalent wind speeds at the site of installation, its costs and also the quality of the manufacturer. For small domestic applications in low wind speed areas, the use of a low-cost wind turbine that can operate in a low wind regime would be desirable. Unfortunately, there are substantial problems in the Savonius rotor. It is worth noting that the performance efficiency is lower compared to the horizontal axis wind turbine as well as negative torque on the return blade.

The Savonius turbines have a self-starting speed in urban area under low wind speed, but the main problem that causes the reduced performance efficiency of the Savonius rotor is that it has a high negative torque at the return blade. Therefore, the design and testing of three-dimensional models of Savonius (vertical axis wind turbines) printed in this work are presented, by the focus on the geometric parameter of the blade shape and improve the gap between the two blades.

### 1.3 Objectives

The goal of this study is developing Savonius blades an effective and easy to fabricate by using 3D printer technology, also by a low-cost method of recording the experimental data. Therefore, this thesis embarks on the following objectives while achieving the aim of this research:

1. To determine the best of overlap ratio (OR), which affecting on Savonius wind turbine performance.
2. To develop a blade shapes by modifying the concave blade surface as a zigzag surface to increase positive torque and adding four bypass channels in each blade.
3. To compare the new model with a publisher previous model in terms of power coefficient and torque coefficient.

### 1.4 Scope of Study

The scopes of this research are set forth as follows:

1. Validation and verification of the 2D unsteady simulations (CFD-Fluent) of the Savonius elliptical turbine to determine the effect of the turbulence models, overlap ratio, and a number of elements (Mesh Ansys). Given the results of the numerical simulation, geometry parameters were adopted to design three models of the blade to prepare it for experimental work.

2. Design new Savonius turbine models based on the optimum parameters by researches and previous studies, drawing the models using the SolidWorks program, as shown below:
  - a) Conventional elliptical Savonius turbine was modified by changing the overlap ratio from the value ( $OR=0.15$ ) to ( $OR=0.2$ ) and called as the Model-A.
  - b) The concave surface of the blade Model-A was modified (as zigzag shape) to increase its surface area and called as Model-B.
  - c) The blade shape of the Model-B was modified by adding bypass channels for each blade to creating new configuration was called the Model-C.
3. Manufacturing the new models of the Savonius rotor after obtaining optimal parameters by using the 3D printer technology for the purpose of experimental testing.
4. An experimental test of the new models via open wind tunnel subsonic at different values of wind speeds in order to obtain the values of the maximum power coefficient. New method is used to record experimental data by making a digital control panel.
5. Comparative of the results of the experimental test with 3D unsteady simulations (CFD-Fluent version 19.1).

### 1.5 Outline of the Study

The thesis has been organized into five chapters, the details of which are summarized below:

**Chapter 1:** This chapter presents the background of the wind turbine and the current issues related to this study.

**Chapter 2:** This chapter presents the principle of the work of the Savonius turbine as well as an overview of previous researches in this area.

**Chapter 3:** This chapter illustrates the research methodology applied in this study which includes five subtopics such as 2D unsteady simulation of the geometry parameters for their adoption in this study; the manufacturing of new models;
